**COLLEGE OF ARTS & SCIENCES**

## Executive Summary

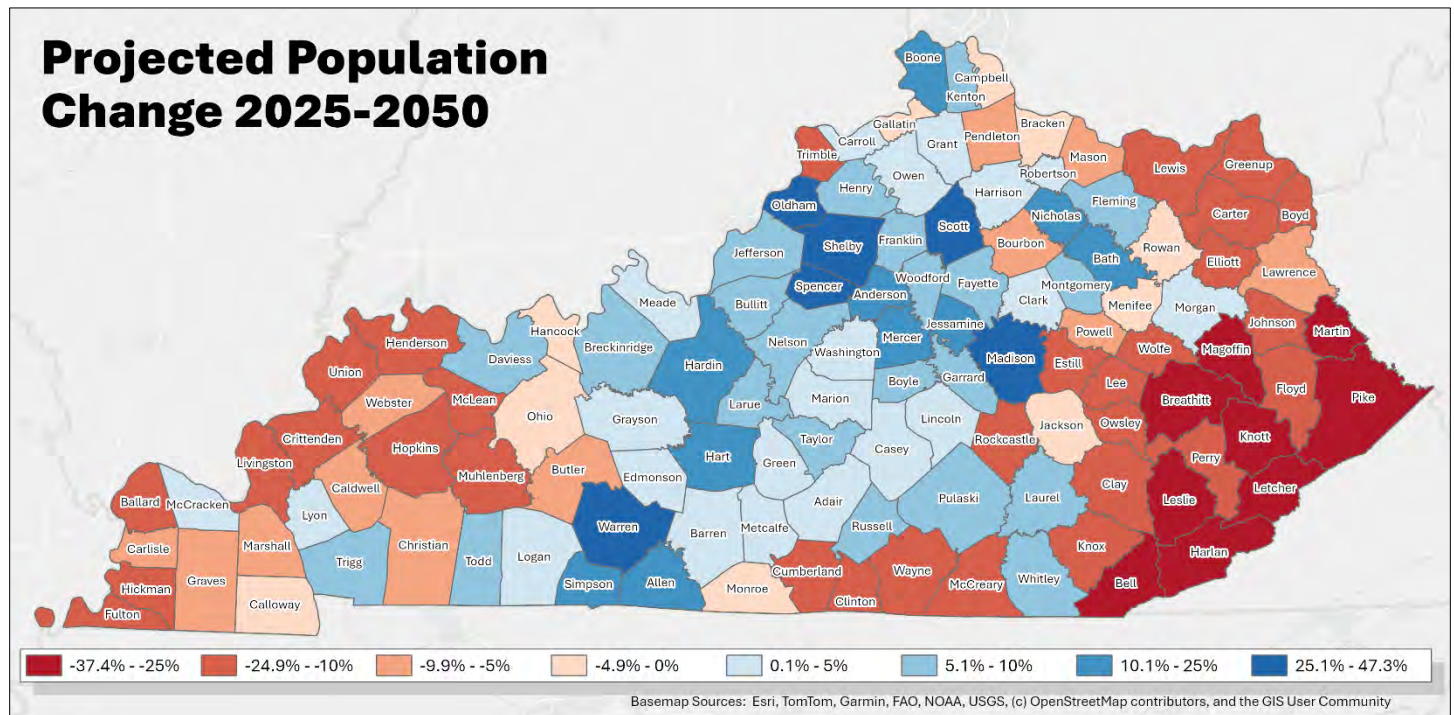

This report contains population and household projections for the state of Kentucky, all 120 Kentucky counties, and Kentucky’s 15 Area Development Districts over the 2025 to 2050 period. These projections supersede those in the previous (v2022) release.

Between 2025 and 2050, the population of Kentucky is projected to increase by 5.1% — from 4,606,864 to 4,840,745 — a gain of 233,881 residents. The number of households in the state is projected to increase 7.7% during this time — from 1,851,015 to 1,994,121 — a faster rate than the population itself. Together, these rates imply a continued future decline in mean household size.

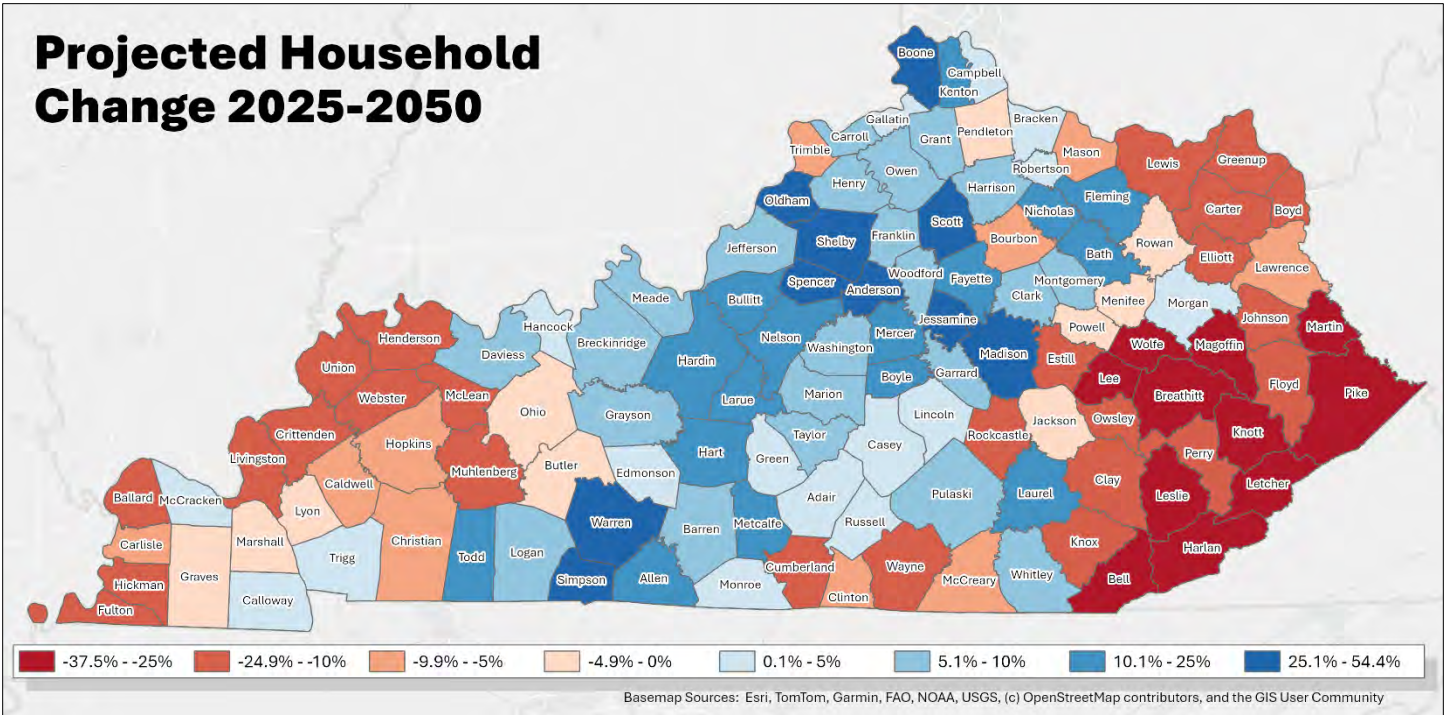

The 5.1% projected population growth is approximately one-half a percentage point higher than in the previous set of projections. The new 2050 population projection of 4,840,745 is 55,512 residents greater than the prior projection of 4,785,233. This change is primarily the result of increased net migration over the 2020-2025 period.

Of Kentucky’s 120 counties, 59 are expected to exhibit population gains between 2020 and 2050. The remaining 61 counties are forecast to lose residents through a combination of population aging, which leads to negative natural change, and persistent outmigration. Jefferson and Fayette Counties are projected to remain the most populous counties in 2050, with populations of 835,438 and 361,922, respectively. Warren County is expected to surpass Kenton County to become the state’s 3rd most populous, with 220,072 people. Robertson, Owsley, and Hickman Counties will remain the state’s least populous in 2050, with fewer than 3,500 residents each.

Largest Projected County Population Gains and Losses 2025-2050								
	Percentage Gain		Numeric Gain		Percentage Loss		Numeric Loss	
1.	Warren	47.3%	Warren	70,697	Letcher	-37.4%	Pike	-19,176
2.	Scott	46.1%	Jefferson	40,216	Pike	-35.0%	Floyd	-8,434
3.	Madison	35.1%	Madison	35,662	Leslie	-34.8%	Harlan	-7,466
4.	Shelby	28.6%	Boone	33,914	Knott	-34.8%	Letcher	-7,460
5.	Spencer	28.2%	Fayette	32,171	Martin	-33.7%	Henderson	-7,377

# Projected Household Change 2025-2050

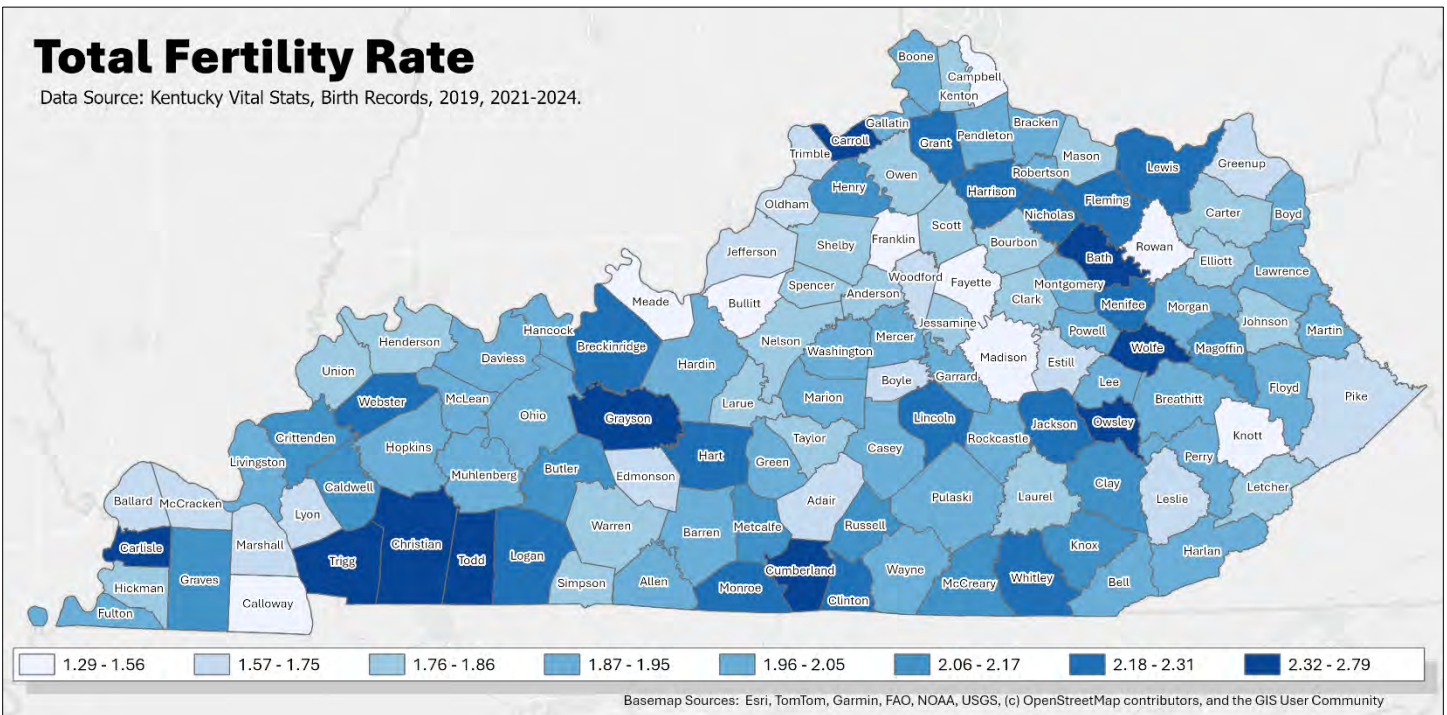

## Components of Population Change

Population projections are based on vital statistics rates in place at a given time. The maps on the following pages display current summary measures by county of the three components of population change: births, deaths, and migration. These measures are the basis for the population and household projections contained in this report.

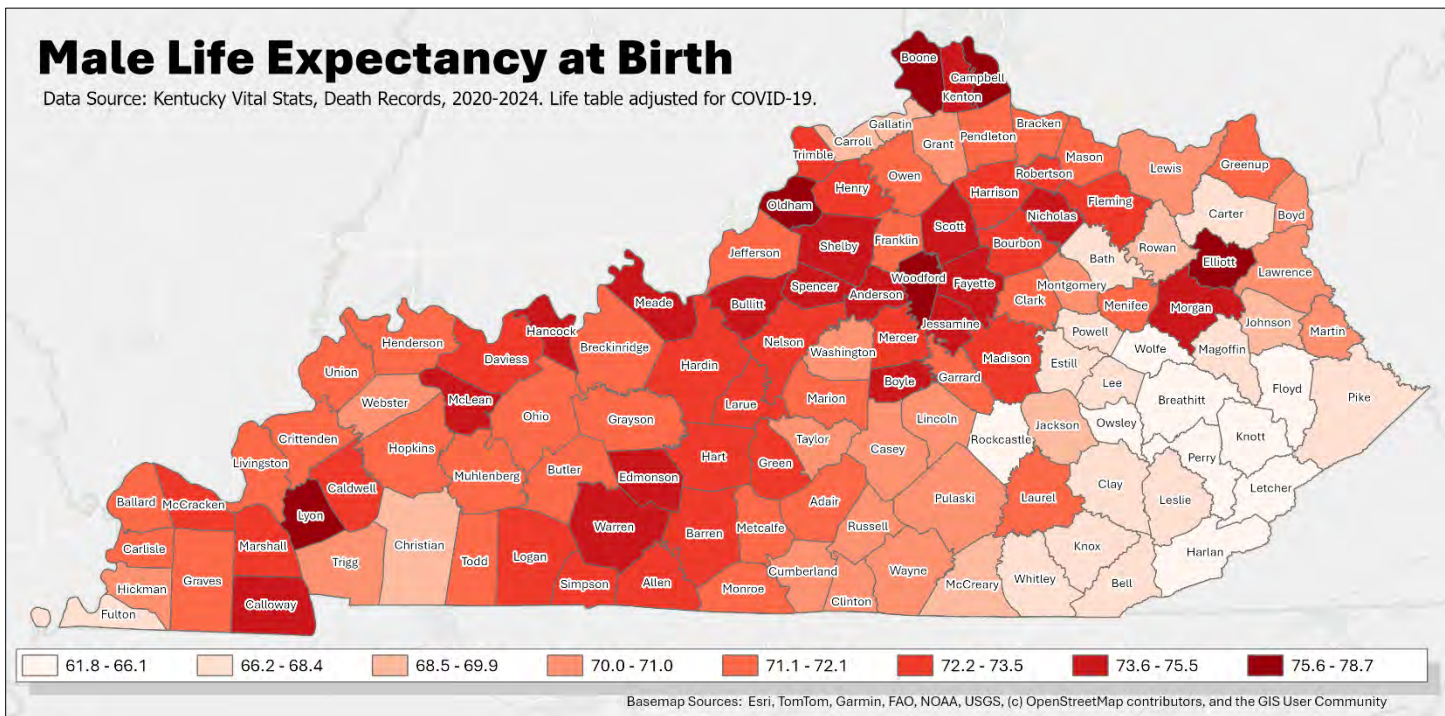

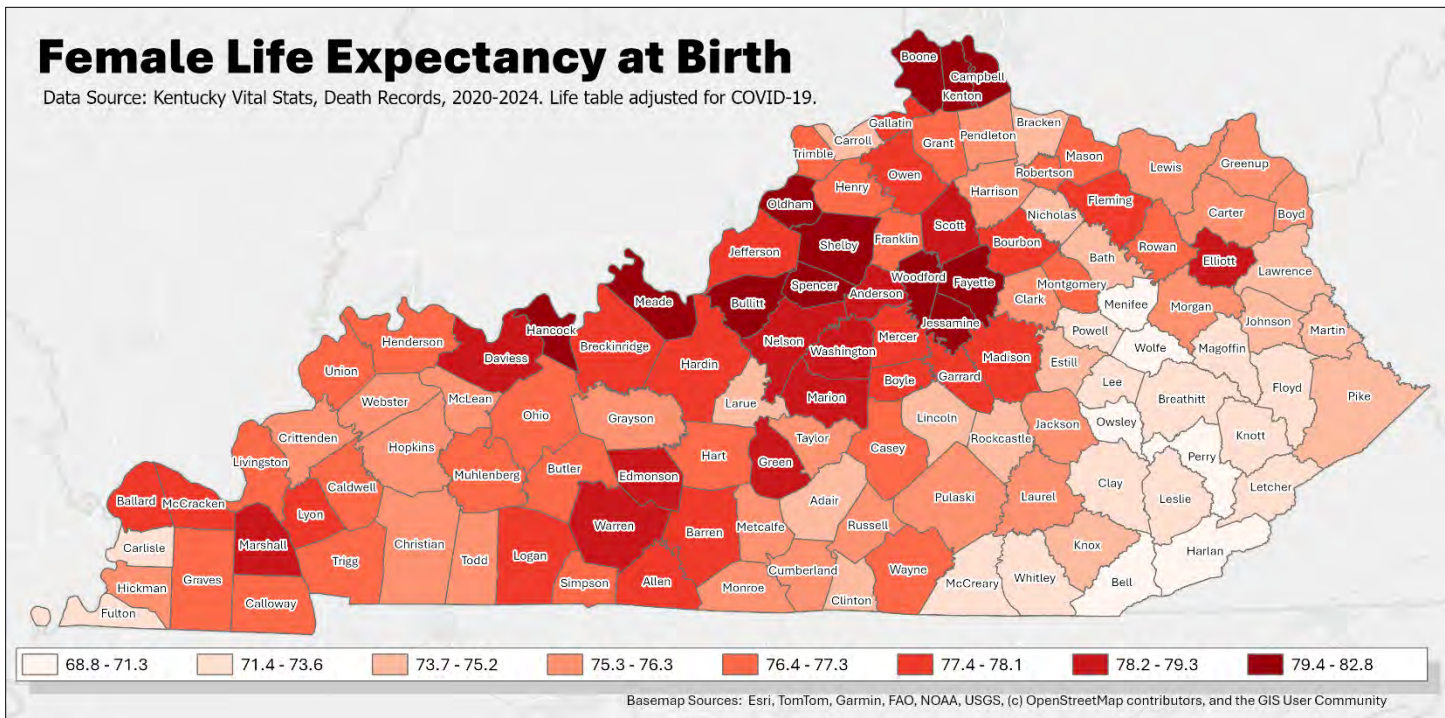

The **total fertility rate** (TFR) is the number of children that the average woman would bear if she survived through her childbearing years, exhibiting the age-specific fertility rates in place at the present time. In familiar terms, it's the mean number of children born to each woman in the population. The TFR for Kentucky is currently 1.80.

## Total Fertility Rate

Data Source: Kentucky Vital Stats, Birth Records, 2019, 2021-2024.

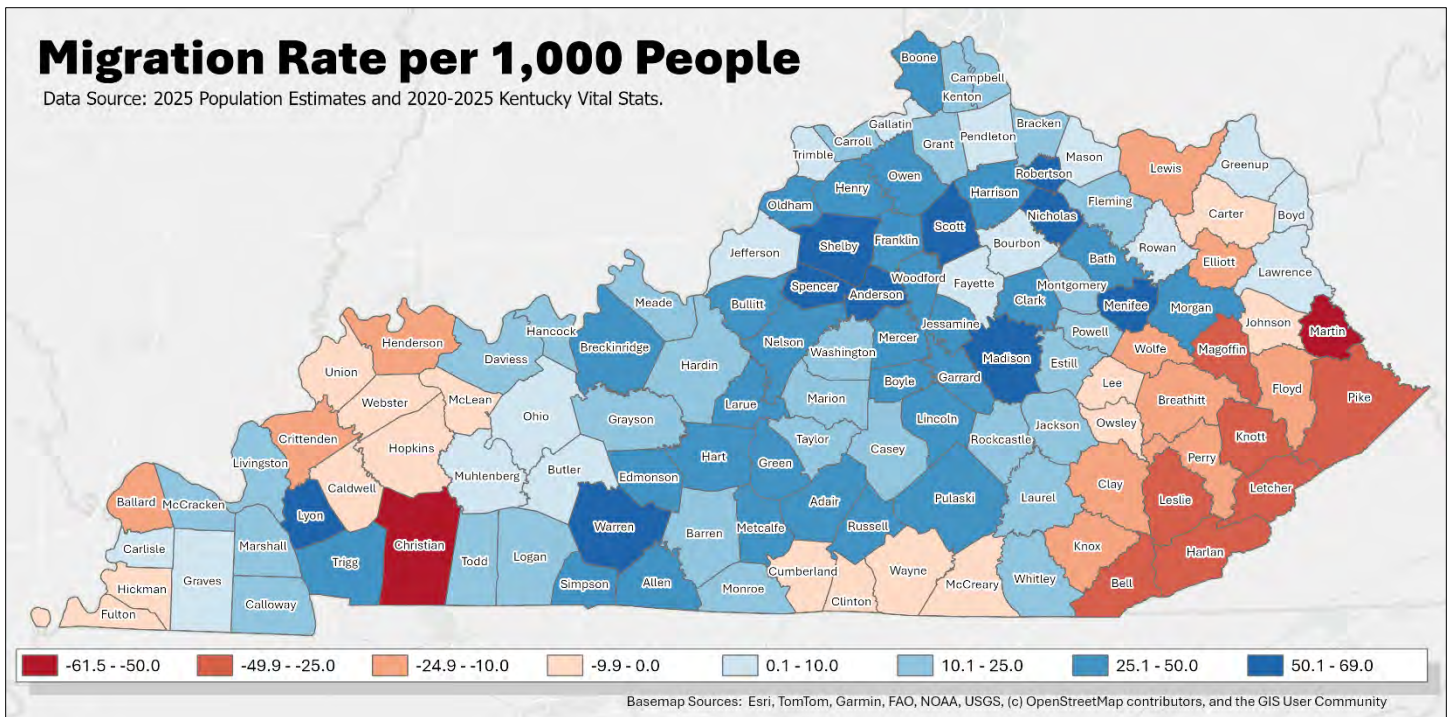

**Life expectancy at birth** is the number of years that the average person born today would live if they exhibited the current age-specific survival rates throughout their lifespan. This figure tends to vary widely between females and males. Although the data used to calculate these life expectancies covered the period with high prevalence of COVID-19, they were adjusted to account for these excess deaths. See the *Methodology* section of this report for more detail. The current life expectancy for Kentucky females is 77.4 and the current life expectancy for Kentucky males is 72.2.

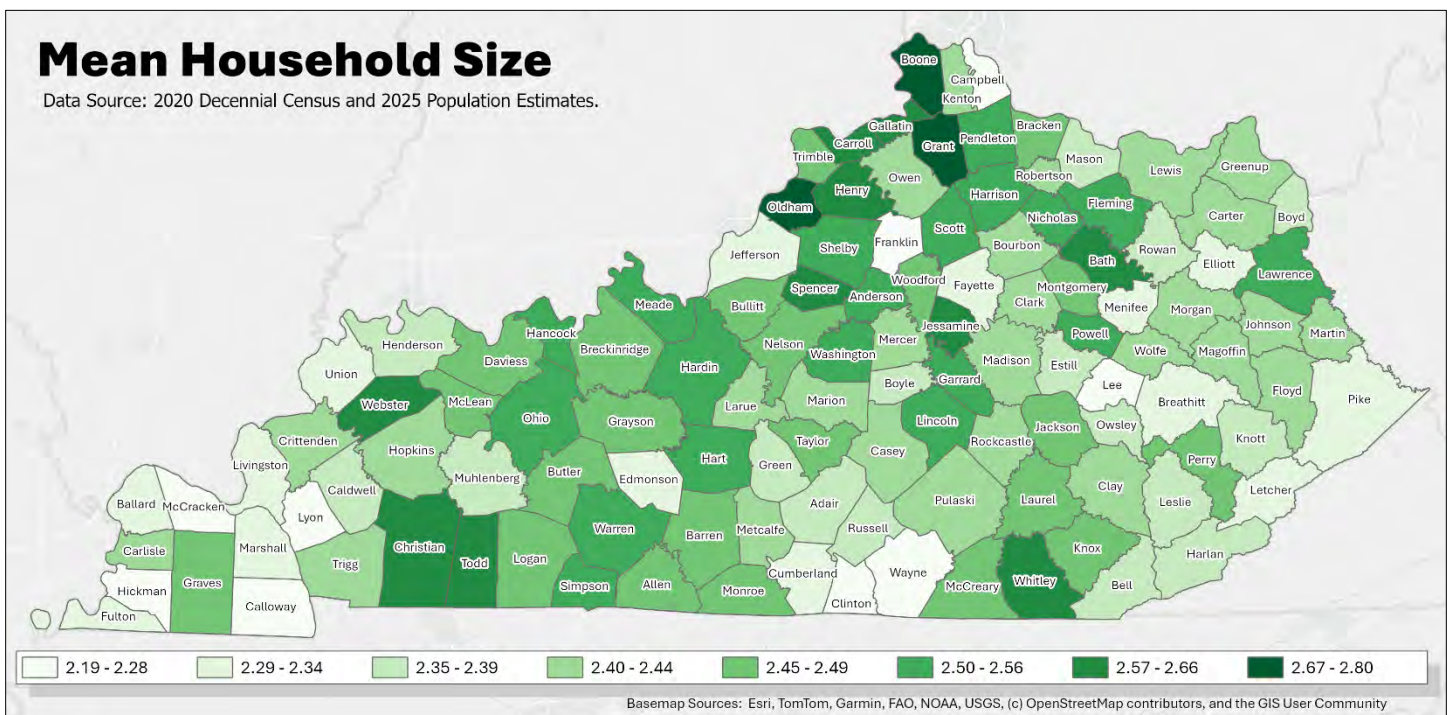

Note that maps above do *not* use the same age class (color) breaks.

**Net migration** is the total number of persons moving into an area minus the total number of persons moving out of the area. The net migration rate shown here is calculated as the estimated number of net migrants per 1,000 residents. It includes people moving between a county and another county, as well as people moving between a county and other states or countries. The estimated net migration rate for the state is 25.7 per 1,000 residents.

The **mean household size** is the total number of persons living in households divided by the total number of households. A household is all of the individuals living within a single housing unit or address point, regardless of their relationship to one another. The calculation of household size excludes individuals living in uncommon, or group, living situations, such as college dormitories, senior facilities, prisons, and military installations. The current mean household size in Kentucky is 2.42.

## Methodology

Population projections are forecasts of the population in future time periods. Using a model that integrates recent historical data and standard demographic processes, estimates of future population are generated based on historic patterns. The most common population projection model used by demographers—the cohort component model—was used to generate the projections in this report. This model captures the impact of the primary components of population change – births, deaths, and net migration – in order to forecast changes in future population (see Formula 1).

The cohort-component model is based on the balancing equation of population growth:

$$N_{t+5} = N_t + (B_{t,t+5} - D_{t,t+5}) + (IM_{t,t+5} - OM_{t,t+5}) \quad (1)$$

where  $N_t$  is the total population at time  $t$  (the start of the forecast period),  $B_{t,t+5}$  is the number of births between time  $t$  and time  $t + 5$ ,  $D_{t,t+5}$  is the number of deaths between time  $t$  and time  $t + 5$ , and  $IM_{t,t+5}$  and  $OM_{t,t+5}$  are the numbers of in-migrants and out-migrants between time  $t$  and time  $t + 5$ . The output from this equation,  $N_{t+5}$ , represents the total population forecast at time  $t + 5$ .  $B_{t,t+5}$ ,  $D_{t,t+5}$ , and  $(IM_{t,t+5} - OM_{t,t+5})$  are derived by applying recent fertility, mortality, and migration rates to the population by five-year age group at time  $t$ . The model was carried out over five-year periods from 2020 to 2050.

These projections were made using a “bottom-up” approach, in which the county projections were generated first and then aggregated to create projections for the Area Development Districts and the state. County-level estimates from the Census Bureau’s 2025 Population Estimates Program served as the base population. Because age and sex breakdowns for these estimates are not yet available, the age and sex population shares from the 2024 Population Estimates Program were applied to the total 2025 counts. The most currently available fertility, mortality and migration rates were then used to project the change in each age cohort moving forward.

### Fertility

Age-specific fertility rates were calculated for each county using birth data provided by the Kentucky Cabinet for Health and Family Services. These fertility rates are derived from data from 2019 and 2021-2024. The number of births in calendar year 2020 demonstrated a notable reduction from those in 2019 and 2021—likely related to the COVID-19 pandemic—and were thus excluded from the data. The numerators for the fertility rate calculations are the total births during these five years to women in each five-year age group beginning at age 10 and ending at age 55 (e.g., 10-14, 15-19, ..., 50-54). Births that were missing the county identifier were allocated to counties based on the proportion of known births within the county. Births that were missing the age identifier were allocated to ages within the county based on the proportion of known births within each age group within the county. Births that were recorded to women younger than age 10 or older than age 55 were considered missing and were allocated as above; these ages are likely to have been miscoded.

The denominators for the fertility rate calculations are the total life-years lived by women in each five-year age group in each county. The number of life years lived in each age group is estimated as five times the mean of the 2019 population estimate for the age group (from the intercensal estimates) and the 2025 population estimate for the age group (from the vintage 2025 estimates). Although age-specific fertility rates for small counties may be somewhat unstable due to the small number of births and small populations within each five-year age group, this instability is unlikely to have a dramatic effect on the final projections.

Because fertility may exhibit a downward (or upward) trend over time, the calculated fertility rates are allowed to vary in future projection periods. Extrapolation of county-specific rates proved to be unreliable, so the state trend in fertility was used to adjust the county-specific rates. State-level age-specific fertility rates were calculated for each year from 2000 to 2024 – this fertility pattern was then extrapolated via a logarithmic function through 2050. The 2050 state-level age-specific fertility rates were set as “anchors” for the future county-level fertility rates. The figure below displays the estimated and projected state-level age-specific fertility rates from 2000 to 2050.

Actual (2000-2024) and Projected (2025-2050)  
Age-Specific Fertility Rates for Kentucky

Note that the 10-14 and 50-54 age groups are not shown in this graph because their rates are effectively 0. Given the pattern of declining fertility at younger age groups, county-level fertility rates for ages less than 30 that were higher than the state anchor were forecast to decrease towards the anchor. Fertility rates that were already below the state anchor were maintained at their present level. County-level fertility rates for ages 30 or greater that were lower than the state anchor were forecast to increase towards the anchor. Fertility rates that were already above the state anchor were maintained at their present level. The projected age-specific, county-specific fertility rates in 2030, 2035, 2040, 2045, and 2050 were then used in the cohort component model.

### Mortality

Age-specific survival rates were calculated for each county using life tables based on death data provided by the Kentucky Cabinet for Health and Family Services from the period 2020-2024. The initial mortality rate within each five-year age and sex group was calculated as the number of deaths occurring in that group divided by five times the mean of the 2020 and 2025 population estimates for the age group (from the vintage 2025 estimates).

As in the birth data, deaths that were missing the county identifier were allocated to counties based on the proportion of known deaths within the county. Deaths that were missing the age or sex identifier were allocated to ages or sexes within the county based on the proportion of known deaths within each age or sex group within the county. Deaths that were recorded at ages greater than 110 were considered missing and were allocated as above; these ages are likely to have been miscoded.

COVID-19 had a significant and unusual impact on mortality during this time. Removing deaths caused by COVID-19 from the records is inappropriate, as doing so implies that the individuals succumbing to COVID-19 would have otherwise survived through the period. Instead, a cause-deleted life table is used to calculate the survival rates. In the cause-deleted life table, decedents for whom COVID-19 was listed as the leading cause-of-death are instead subjected to mortality from all other causes. The survival rates from this method are interpreted as the survival rates that would have been in effect if COVID-19 had not occurred. Survival rates were held constant throughout the projection period. Although age-specific survival rates for small counties may be somewhat unstable – due to the small number of deaths and small populations within each five-year gender-age group – this instability is unlikely to have a dramatic effect on the final projections.

### Group Quarters

Prior to the estimation of the migration component of the model, the total population was disaggregated into a household population segment and a group quarters population segment. The group quarters population—which

includes individuals living in college dorms, senior living facilities, prisons, and military installations—is likely to exhibit migration rates that are dissimilar to the rest of the population. This disaggregation was carried out so that population mobility within these two segments could be modeled separately. Such a disaggregation cannot be accurately carried out for the fertility and mortality components, as it is not possible to separately identify births and deaths accruing to the two different segments of the population.

Group quarter populations are not available by five-year age and sex in 2025. To generate the current breakdown of the group quarters population within each county, the proportion of the total group quarters population within each five-year age-sex group in the 2020 Decennial Census is applied to the total group quarters population from the 2025 population estimates. The five-year age- and sex-specific household populations are then calculated as the total populations within each group minus the group quarters population within each group.

Change in the group quarters population may occur for reasons exogenous to those typically accounted for in a cohort-component population model, such as growth in college enrollments. Although it would be ideal to apply separate growth rates to distinct situations (e.g., dorms or prisons) or to specific age or sex groups, this level of detail is unfeasible. Instead, each county-, sex-, and age-specific group quarters population is assumed to grow 1% over each five-year projection period. This assumption results in a group quarters population in 2050 that is an equivalent percentage of the population as it was in 2025.

### **Migration**

Migration is the most difficult component of population change to measure, as the data necessary to do so are often unavailable. Rather than estimating in-migration and out-migration as two separate processes, population mobility here was estimated only as net migration (which may be positive or negative). A residual method of estimating net migration was used, in which a five-year age-sex population (e.g., 10–14-year-old girls) was compared to the succeeding five-year age-sex population five years later (e.g., 15–19-year-old girls). Any difference in these population figures not attributable to mortality was attributed to migration and became the number of net migrants for this age-sex group. Special methods were used to determine the number of net migrants for the youngest (age 0-4) and oldest (85+) age groups.

The net migrant estimates were used to calculate age- and sex-specific migration rates for each county by dividing each estimate by the number of life years lived by individuals in the age-sex group. Life years lived were calculated the same as for the fertility and mortality components above. Because migration can be especially unstable, the residual method detailed above was carried out for the five-year period 2020-2025 and for the five-year period 2015-2020. The mean migration rates for these two periods were used as the final age-, sex-, and county-specific migration rates in the cohort component model; they were held constant throughout the projection period.

### **Households and Household Size**

To determine the projected number of households, the headship rate method was used. Using data from the 2020 Decennial Census, the proportion of the household population classified as the head of household within each 10-year age group and each county was calculated. These headship rates were then applied to the household population estimate for each age group and county in 2025 and in each succeeding projection year. This method assumes that the headship rates remain constant over time. The projected mean household size was calculated as the projected population in households divided by the projected number of households.

### **Race and Ethnicity**

Projections by race and ethnicity were carried out in the same manner as detailed above, except that the sex- and age-specific population was disaggregated into four exclusive and exhaustive groups based on race ethnicity: white non-Latino, Black non-Latino, Latino/Hispanic, and other race non-Latino. This last group includes all individuals reporting an ethnicity of non-Latino/Hispanic and a race of American Indian or Alaska Native, Asian, Native Hawaiian or Other Pacific Islander, Some Other Race, or Two or More Races. Births were assumed to be of the same racial/ethnic categorization as the mother.

Projections by race and ethnicity were generated only for the state of Kentucky and for the Area Development Districts. Extremely small populations within some race/ethnicity groups preclude such projections being accurately generated for individual counties.

The projections by race and ethnicity were generated for the Area Development Districts first, and these counts were aggregated to obtain the state counts. These projections rely on different rates than those used in the total population projections and thus will not sum exactly to the projections generated from the county-level data detailed above. To maintain consistency between the two sets of projections, the projections by race/ethnicity are controlled to the total population counts for the state and each of the ADDs. The raking procedure used to accomplish this may introduce small rounding errors into the projections.

### **Impact of COVID-19**

Although these projections rely on demographic change that occurred during the COVID-19 pandemic, adjustments were made to mitigate the impact of the pandemic on the calculated demographic rates. However, deviation from these underlying demographic patterns that are the result of societal changes in behaviors, potentially as a consequence of COVID-19, will necessarily not be accounted for in these projections. It is too early to know whether COVID-19 has caused any long-term changes in these patterns, particularly in the areas of fertility and migration.

### **Description of Tables and Graphs**

The pages that follow present results for the state, Area Development Districts, and counties. These pages have a consistent format. The first table displays the counts and projections of total population, household population, group quarters population, and households within the area between 2010 and 2050. The population change table shows change in the area between 2020 and 2025 and the various components underlying that change. Population change between 2010 and 2020 is also shown for comparative purposes. The vital statistics table summarizes the vital statistics (from the past five years) that were used to generate the population projections. Note that the migration rates included here are simplified versions of the migration rates used in the projections, which are different for each sex and age group.

The population projection graph displays the Decennial Census populations and estimates for 2025 and before (blue) and the new population projections (red). The graph also includes the prior (vintage 2022) population projections (pink) for comparative purposes. Of particular interest is the difference between the 2025 value of the blue dot—the current population estimate—and the 2025 value of the pink dot—the prior projection. Variation between the current and prior projections is heavily influenced by this difference, itself the result of changes in demographic rates between 2020 and now.

The “Age and Sex” page displays population pyramids for each area in 2025 and 2050. A population pyramid shows the percent of the total population in an area that lies within each sex and five-year age group. These charts highlight the specific ways that an area’s population is changing. Note that the grey bars in the population pyramids represent population living in group quarters.

An additional page for the state and ADD areas shows projections by race and ethnicity. The first race/ethnicity table shows the populations and projections for each of the four groups, while the second table highlights the percent of the total population within each of the four groups. The race and ethnicity projections graph displays the Decennial Census populations and population projections for each of the groups.
